### **ADMINISTRATIVE INFORMATION**

The work reported in this report was done under the Communications and Networking block program, Independent Exploratory Development (IED) project ZE91, "Automatic Package Specification Generator for Bit-Oriented Messages." The work was done in FY90 by R. H. Mumm and S. A. Parker of the Computer Systems and Software Technology Branch, NOSC, Code 411.

Released by  
D. L. Hayward, Head  
Computer Systems and  
Software Technology  
Branch

Under authority of  
A. G. Justice, Head  
Information Processing  
and Displaying Division

### **ACKNOWLEDGMENTS**

The authors wish to acknowledge Dr. Charles Sampson, Computer Science Corporation, and Dr. Michael Shapiro, Naval Ocean Systems Center, for reviewing this document and providing valuable comments.

A special thanks to Michele Kendall, Naval Ocean Systems Center, for graciously doing the word processing required for this document, and to Bob Ollerton, Naval Ocean Systems Center, for technical assistance.

## OBJECTIVE

Our objective was to develop a portable software tool that automatically generates the Ada source code to define bit-oriented messages. This tool can help reduce development costs for command and control systems and other Ada software that process bit-oriented messages.

## RESULTS

We designed, coded, and demonstrated the Bit-Oriented Message Definer (BMD) tool. The tool compiles and executes in the Vax Ada, Sun Telesoft, and Sun Alsys environments and generates message definitions for five target environments. A preliminary version was used to generate approximately 7000 Ada source lines of code for the Ada Bit-Oriented Message Handler (ABOM) Project.

## RECOMMENDATIONS

1. Programmers who are developing Ada software that process bit-oriented messages should try using the BMD. BMD can reduce development time.
2. Ada compiler validation testing needs to be more comprehensive. Validation testing currently does not test representation specifications but needs to. During testing of the BMD, problems were found with the representation specifications for two validated compilers.
3. Automatic code generation can be used effectively for Ada applications. The automatic code is most appropriate when the source code is repetitious and writing it manually is labor intensive.
4. Even when writing small programs a design methodology should be used. Small programs frequently expand. A good design facilitates changes, maintenance, and reuse.

## INTRODUCTION

The Bit-Oriented Message Definer (BMD) is a portable interactive software tool for automatically generating Ada source code that defines bit-oriented messages. The BMD can help reduce the development costs for Ada software that processes bit-oriented messages. Appropriate applications include command and control systems, such as, the Command and Control Processor (C<sup>2</sup>P) Shadow Project, which is being directed by Naval Ocean Systems Center (NOSC) and the Ship Gridlock Project, which is being conducted at the Naval Surface Warfare Center (NSWC), Dahlgren, VA.

The BMD executes on the Vax Ada, Sun Telesoft Ada, and Sun Alsys compilers and generates source code that will execute in at least five different target environments.

The BMD automatically generates the Ada source code that a programmer would otherwise need to manually generate. This manual process is time consuming and requires specific knowledge of the target computer and compiler. Information the programmer would have to know includes how bits are numbered, how they are ordered, the size of type integer, as well as other details. The BMD user does not need to know these differences. The source code for the message definitions is generated automatically for the target environment the user selects. The BMD user simply defines the messages by looking at pictures of message layouts in software specification documents and then by responding to interactive program prompts. The user needs only a minimal knowledge of Ada.

## BACKGROUND

The BMD tool was developed as an Independent Exploratory Development project at NOSC. A need for this tool was identified during the development of software for the Ada Bit-Oriented Message Handler (ABOM) project, carried out by Science Applications International

Corporation (SAIC) under the direction of NOSC, Code 411. ABOM software processed hundreds of bit-oriented messages. These included link-11, link-4a, link-16, as well as, Combat Direction System (CDS) messages. Writing the message definitions in Ada by hand was labor intensive, repetitious, and tedious. Errors were easily made. We determined the message definition process could be rapidly and accurately done by automating it. Preliminary BMD work began during the development of ABOM software.

The approach taken to develop BMD was to collect the definitions of bit-oriented messages from actual Ada projects. These projects were

1. AN/WSN-5 Inertial Navigation System (INS) developed by the Software Engineering Institute (SEI)
2. Command and Control Processor (C<sup>2</sup>P) Shadow developed by the Hughes Aircraft Corporation and Syscon Corporation for NOSC, Code 411
3. Ada Bit-Oriented Message Handler (ABOM) software developed by SAIC for NOSC, Code 411

The BMD was developed to be general purpose, allowing messages to be defined in different ways. The BMD provides the capability for defining messages required for these projects and other applications.

## KEY FEATURES

### HOST ENVIRONMENTS

Vax Ada

Sun Telesoft

Sun Alsys

BMD is a very portable tool. BMD will compile and execute in these environments.

## TARGET ENVIRONMENTS

Vax Ada

Sun Telesoft Ada

AN-UYK/43 Ada\_L

AN-UYK/44 Ada\_M

Sun Alsys Ada

- g. Writes descriptive header to package specification

The header gives the user name, output file name, name of target environment, the date and time the package specification was created and other relevant information.

## CHARACTERISTICS OF THE BMD

- a. Provides capability for defining different size messages whose fields vary in length
- b. Allows discriminated records to be defined

This feature is useful when messages have many common fields.

- c. Allows multiple messages to be defined in one package
- d. Provides capability for assigning default values to fields

Default values can be assigned in base 2 through 16 using *Ada-like* notation.

- e. Allows use of field types defined in global or definitions packages.
- f. Does extensive error checking

Error checking includes (1) examining the validity of file names, (2) checking field names, package names, and type names to determine if they are valid Ada identifiers, (3) checking field position to ensure previously defined fields are not overlaid, and (4) determining if the size of a default integer is too large for the field size. Error messages are displayed to allow the user to make corrections.

## CHARACTERISTICS OF SOURCE CODE GENERATED

- a. Defines messages as records

Record representation clauses are automatically generated to specify the order, position, and size of message fields.

- b. Defines message fields to be integer types

Message fields are defined to be integer types of the appropriate size for the field widths. The integer type statements and length clauses are generated automatically.

- c. Aligns records on word boundaries

## TOOL LIMITS

- a. Maximum number of messages allowed in a package specification: 200
- b. Maximum number of bits in a message word: 64
- c. Maximum number of bits in a message: 10,000
- d. Maximum field size: 32 bits
- e. Maximum identifier length: 80 characters

Note: These limits are declared in package `Spec_Gen_ada`

## EXAMPLES

The use of BMD will be illustrated with two examples. The first example is the definition of two INS messages. The second illustrates the use of a discriminated record to define three dummy track messages.

### INS MESSAGES EXAMPLE

In this example, the Time and Status Message and Attitude Message are defined first for a Vax Ada target environment and then for a Sun Alsyl target environment. This example illustrates the difference in the source code generated for these targets.

Figure 1 shows the message layout for the Time and Status Message while figure 2 depicts the layout for the Attitude Message. These are actual message formats taken from the interface design specification document for the INS (NAVSEA, 1982).

Figure 3 shows the BMD prompts and user inputs to generate these message definitions for a Vax Ada target environment. All user inputs are shown in *italics*. The user, Hans, entered run

BMD to begin execution. Hans then entered his name and selected Vax\_Ada as the target environment. He indicated the output file name was INS\_File, that the number of bits in a message word is 16, the package specification created will be named INS\_Spec, the message group name was INS, the message objects will be defined, and the Time\_and\_Status and Attitude message will be created. The fields in the message were defined

Bits

Bits

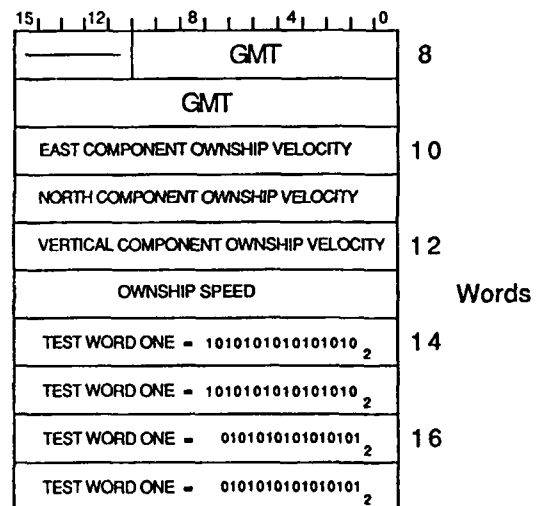

Figure 2. (Continued) Attitude message for the AN/WSN-5 inertial navigation set.

```

run bnd
Enter user name >Hans
Enter target environment
(VAX_ADA, ADA_L, ADA_M, SUN_TEL, SUN_ALSYS)>vax_ada
Enter name of file that will contain specs >INS_File.
Enter number of bits in a message word >16
Enter name of package specification to create >INS_Spec
Enter name of message group >INS
Create message objects (Y or N)? >y
Enter message names in msg group. Enter ';' for last msg.
    1 >Time_and_Status
    2 >Attitude
    3 >;

```

You are now ready to enter fields for all messages.  
Enter ';' for last field.

```

The package specification INS_Spec includes the INS messages below.
Time_and_Status
Attitude
The file you created is :INS_File.
Bit-Oriented Message Definer (BMD) has completed.

```

Figure 3. (Continued) Prompts and user input for time and status and attitude message for Vax Ada target.

by giving them a field name, an optional type defined in another package specification, and an optional field value. If an optional Package\_Name.Type\_Name is not given, then the field will be of an integer type defined in package INS\_Spec. Some fields, such as Message\_Type and Number\_of\_Words were given default values in *Ada-like* notation. Base values of 2 through 16 are valid. Each field position is specified by giving both the field start word, start bit position, and end word, end bit position. To complete the Time and Status message, Hans entered a ";" for FIELD\_NAME. In the BMD a ";" is a delimiter indicating there is no more data of the type being entered. Information was entered in similar fashion for the Attitude message. The output file, INS\_File, was created and the BMD run completed when ";" was entered for FIELD\_NAME for the Attitude message.

Figure 4 depicts the Time and Status and Attitude Message definitions for a Vax Ada target environment. Note the header information

containing the user name, file name, target environment, message word size, and time created. Below the header are the type for integer types ranging from 1 bit up through the maximum size of the predefined type integer for the target environment, which is  $2^{31}-1$  for Vax Ada. The messages are defined as records. Record representation clauses are used to specify the position and size of message fields.

Figure 5 shows the Time and Status and Attitude Message definitions for a Sun Alsys target environment. The user inputs to generate these definitions were identical to those that generated the Vax Ada definitions, figure 3, except now the user specified that the target was the Sun Alsys. The bit positions relative to the zero storage unit in the record representation clause in figure 5 are different than those for the Vax target shown in figure 4. This difference occurred because the Sun orders bits within a word from left to right whereas the Vax orders bits within a word from right to left.

```

## DUMMY TRACK MESSAGES EXAMPLE

Figures 6, 7, and 8 show the message layout for the Dummy Air Track Message, Dummy Surface Track Message, and Dummy Subsurface Track Message. These are fictitious messages created for illustration purposes only. In these messages the fields in each are identical down through CAL CONST. Beyond CAL CONST the fields are different. This layout suggests that these messages can be defined as one discriminated record.

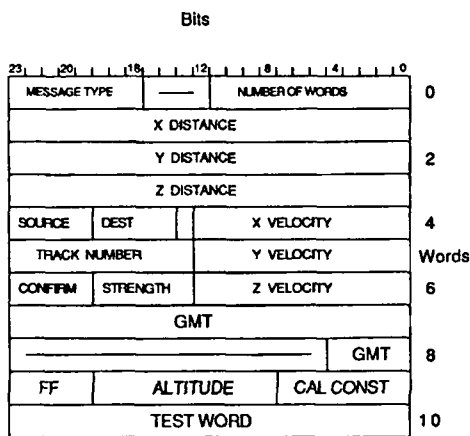

Figure 6. Dummy air track message.

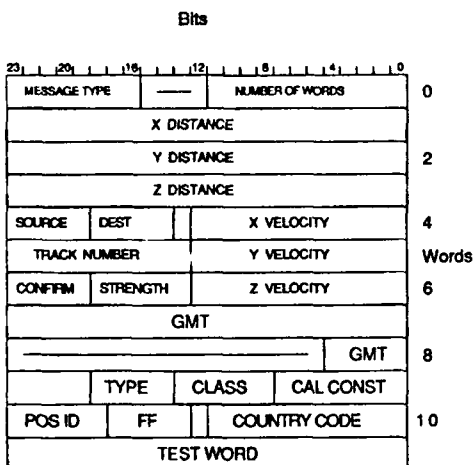

Figure 7. Dummy surface track message.

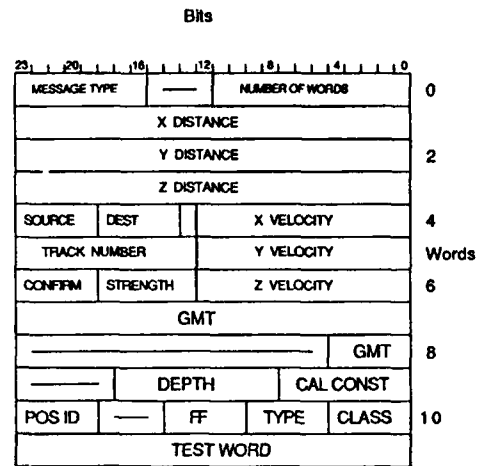

Figure 8. Dummy subsurface track message.

Figure 9 shows the BMD prompts and user inputs used to generate the dummy track message definitions. Again, all user inputs are given in italics. In this example the user, Sally, selected the UYK\_43 as the target, indicates that message size is 24 bits and that message objects will not be created. Sally's responses indicate the message name is Track and will be defined as a discriminated record. She defined the discriminant as Msgs. The user has three choices when defining the discriminant type. It can be (1) of type Boolean, (2) of a type defined in another package specification or (3) of a type defined by the user. When it is defined by the user, the type definition will be declared in the package created. In figure 9, Sally defined the discriminant type as Global\_Data. Message\_Type. Next, the fields, Number\_of\_Words through Cal\_Const are defined to be common to all values of the discriminant. Then Sally indicated the first value of the discriminant is Air, and message fields for the discriminant value Air are Altitude, FF\_A, and TestWord\_A. The same process was followed for the discriminant values Surface and Sub\_Surface. When Sally entered a ";" to indicate there were no more values for the discriminant, the BMD created the output file, track\_file., and the BMD terminated. The fields, Message\_Type, FF\_A, TestWord\_A, FF\_S, TestWord\_S, FF\_SS, and TestWord\_SS were defined to be of types defined in package Global\_Data.

```

run bmd
Enter user name >sally
Enter target environment (VAX_ADA,ADA_L,ADA_M,SUN_TEL,SUN_ALSYS)
>Ada_L
Enter name of file that will contain specs >track_file.
Enter number of bits in a message word >24
Enter name of package specification to create >Track_Message
Enter name of message group >Track
Create message objects (Y or N)? >n
Enter message names in msg group. Enter ';' for last msg.
    1 >Track
    2 >;

You are now ready to enter fields for all messages.
Enter ';' for last field.

Is Message Track going to use discriminated records (Y or N)? >y
What is the Discriminate's name? >Msg

SEI	Software Engineering Institute

## APPENDIX A: LESSONS LEARNED

Lessons were learned in a number of areas during the development, testing, and use of the BMD.

### 1. Reuse

Existing software contributed to the development of the BMD in two ways. First, the Network Architecture Simulated Test and Evaluation Environment (NASTEE) software developed by NOSC, Code 854, provided useful examples of how automatic code generation is done in Ada.

Second, source code was reused from other projects. Code reused included a linked list package from the Event-Activation Record Approach to Simulation Modeling in Ada libraries developed by NOSC, Code 854, and several subprograms for manipulating character strings from the INS developed by the SEI.

The reuse of existing code resulted in faster BMD development with better written components.

The source lines of code for the BMD and source lines of code reused is summarized below.

	Delimiting Semicolon Statements	Comments	Delimiting Semicolon Stmt's & Comments	Card-Image Lines
BMD	1243	344	1587	3380
reused	216	151	367	657

### 2. Tools

The most helpful tools for this project (other than the compilers) were the Vax Ada Debugger and the NASA/Goddard Space Flight Center Standard Pretty Printer. The pretty printer was extracted from the Ada Software Repository (ASR) at White Sands Missile Range, New Mexico. A debugger was not used for development on the Sun but was used for the Vax; the Vax debugging was significantly faster. The pretty

printer was helpful in making the style of the Ada code written by the two authors consistent and in improving the code readability.

### 3. Portability

One goal of the project from the beginning was that the BMD would be 100 percent transportable across the Vax Ada and Sun Telesoft environments, that is, the same software would run in each environment without changing one line of source code. This goal was achieved. Care was taken to not use any software that would limit the BMD to Vax/VMS or Sun/Unix. The BMD has also been successfully compiled and executed in a Sun Alsys environment.

Two potential obstacles to portability were the difference in file names for VMS versus Unix and the difference in the size of the type integer for the two compilers. Type integer is 32 bits for Vax Ada and 16 bits for Sun Telesoft. The difference in file names was handled by examining the contents of System.System\_Name to determine the compiler/operating system BMD was running on.

The difference in the size of type integer for the compilers was handled by declaring the integer type below. The predefined integer type was not used.

```
type Integer_Type is range 0..2147483647;
```

The upper bound on the range is  $2^{31}-1$ . The lower bound is zero because the BMD does not use any negative integers. The Sun Telesoft and Sun Alsys compilers automatically make Integer\_Type of type long\_integer.

Declaring your own type for integer rather than using the predefined integer type is one portability guideline in Nissen, 1988. This guideline and others in Nissen, 1988 were followed. If this guideline had not been followed then the BMD would not have ported from the Vax Ada to the Sun Telesoft environment.

Portability was also ensured by the sequence of demonstrations, that is, there was one on a Vax, followed by a Sun demonstration, and then one on a Vax again.

## 4. Testing

Testing was done by first compiling message definition code generated by the BMD. Then a test program was run that printed out the values of the message fields using the message definition generated by the BMD. This testing was done for each of the target environments. The source code generated for each of the five targets compiled with no errors.

Executing the test program in each target environment has been less successful. The test program executed successfully in the Vax Ada and Sun Alsys environments. It did not execute properly with the Sun Telesoft and ALS/N compilers. The problem with these compilers appears to be the record representation clauses do not work properly.

The test program was run using the Telesoft Version 1.1 compiler for a Sun 386I computer. When using the Telesoft compiler the alignment of fields within a message were displaced 1 byte. A trouble report was submitted to Telesoft's customer service group. A Telesoft representative ran the test program on both the Sun 386I Telesoft and Sun 4 Telesoft compilers. She said the alignment problem is a compiler bug that exists with both compilers and that Telesoft is fixing it.

For the ALS/N compiler, the test program was executed on the AdaVax compiler. A constraint error was raised when the test program attempted to print out a 16-bit test word. An error report has been submitted to the ALS/N program office. Testing involving the execution of Ada\_L and Ada\_M generated object code on the AN/UYK-43 and AN/UYK-44 computers is currently being done.

A lesson learned during testing of the BMD is validation testing for Ada compilers needs to be more comprehensive. The compilers for the five target environments all passed validation. However, three have problems related to record representation specifications. Currently, record representation specifications and other compiler dependent features covered in Chapter 13 of the

Language Reference Manual (LRM), (United States Department of Defense, 1983), are omitted from validation testing. These features must be tested during validation to keep erroneous compilers from going to the field.

## 5. Timing Comparisons – Manual versus BMD

A preliminary version of the BMD was used by SAIC to define bit-oriented messages for the ABOM project. SAIC manually wrote the source code to define link-11, link-4a, and link-16 messages. The CDS message definitions were generated using the BMD. SAIC reported that message definitions were created twice as fast when using the automated tool. SAIC used the tool to generate approximately 7000 lines of source code defining the CDS messages.

One of the authors, (HM), manually wrote the message definitions for four INS messages targeted for the AN/UYK-43 and then generated them using the BMD. The task required 2 hours and 14 minutes to do manually and 25 minutes to do with the BMD. After writing the code by hand, three compilations were required to fix errors. The BMD-generated code compiled error-free the first time.

## 6. Lack of a Formal Design Methodology

No formal design methodology was used in developing the BMD. At the beginning it did not seem necessary. It appeared that the tool would remain small and uncomplicated. However, it grew in size and complexity. Ultimately, the use of a formal design methodology would have made it easier for the authors to change and enhance the code.

## 7. Lack of a Configuration Management Tool

No configuration management tool was used during the development of the BMD. At the beginning it did not seem necessary since only two people would be writing the tool. In hindsight, a configuration management tool would have been useful.
